Skeletal muscle growth is controlled by a combination of genetic program and nutritional status. Although the process of skeletal muscle hypertrophy is not completely understood, it is known that muscle mass and fiber type can be altered, depending on the relative time, and the magnitude of the accretion of muscle mass. With advances in molecular biology and genetic engineering, it has become clear that these factors do not affect all types of muscle in the same manner. For instance, it is not known whether the program of gene expression for the hypertrophic response is the same or different in slow versus fast skeletal muscle or in the myotubes that give rise to them. In addition, although multiple independent signaling pathways control muscle hypertrophy, it is unknown how much of the signaling pathway(s) that affect the process of muscle hypertrophy actually are coupled to the process of myogenesis. It is also not clear what the interrelationship(s) are between pathways that control cell growth, cell metabolism and tissue interactions. This review discusses some of the issues that remain to be addressed in this field and the potential role for Wnt signaling cascades in controlling muscle hypertrophy.Poll : Is your airline's fees hurting you or not?
